Data report overview

The tidy dataset was derived from the original [Human Activity Recognition Using Smartphones Data Set](#) by merging the training and test sets, extracting only the measurements on the mean and standard deviation for each measurement and averaging of each variable for each activity and each subject.

The dataset examined has the following dimensions:

Feature	Result
Number of observations	180
Number of variables	68

Naming convations:

The features selected for this database come from the accelerometer and gyroscope 3-axial raw signals (so with the suffix '-X' we denote the x-axis, with '-Y' the y-axis and with '-Z' the z-axis).

These time domain signals (prefix 'Time-') were captured at a constant rate of 50 Hz. Then they were filtered using a median filter and a 3rd order low pass Butterworth filter with a corner frequency of 20 Hz to remove noise. Similarly, the acceleration signal was then separated into body and gravity acceleration signals ('Time-BodyAcceleration' and 'Time-GravityAcceleration' prefixes) using another low pass Butterworth filter with a corner frequency of 0.3 Hz.

Subsequently, the body linear acceleration and angular velocity were derived in time to obtain Jerk signals (we denote this signals with '-Jerk'). Also the magnitude of these three-dimensional signals were calculated using the Euclidean norm (we denote this signals with 'Magnitude').

Finally a Fast Fourier Transform (FFT) was applied to some of these signals producing frequency domain signals (prefix 'Frequency-').

The set of variables that were estimated from these signals are:

mean(): Mean value (denoted with '-Mean')

std(): Standard deviation (denoted with '-Std')
